

UX/UI Case Study: Atomic Component System & Friction Reduction in Instructor Booking

This case study demonstrates the transition from reactive mockups to a scalable design system: how a specification based on the BJ Fogg Behavior Model ($B = MAP$) and the CREATE action funnel was translated into an atomic component library and a refreshed instructor catalog (Instruktorid).

1. The Problem and Audit Context

The previous version of the "Instruktorid" tab broke the user journey during early instinctual reactions (*Reaction*) and comparative evaluation (*Evaluation*):

- Illusory Social Proof (Low Motivation):** An identical "5.0" rating across all cards with no review counts stripped users of clear quality signals.
- Cognitive Friction (Hard Ability):** Hiding immediate availability required users to click into every single profile to see open dates.
- Fractured Call-to-Action (Broken Prompt):** Inconsistent button styles—a filled blue button on one card versus outline ghost buttons on the other five—destroyed interface predictability.

2. Intern Execution: Component-Driven Mindset

The intern approached the task with a focus on reusability and scalability:

"I only built the cards here, and reused yesterday's layout. I just changed the button color and updated the text in the sorting panel."

Rather than redesigning the entire screen from scratch, the work applied **Atomic Design** principles:

- Core UI Kit with State Coverage:** Established a unified token set (Manrope font, #1668E3 primary and #F5931E CTA accents) with complete interactive states (default, hover, active, focus, disabled, loading/skeleton).
- Atoms & Molecules:** Built modular standalone primitives—category chips, verification badges, availability indicators (Vaba täna, Järgmine: 12. sept), and rating blocks with real review counts.
- Organisms (Cards & Filters):** Structured the instructor card as a resilient organism capable of handling varied data scenarios without broken layouts.

3. Before vs. After Comparison

Element / Aspect	Baseline State (Legacy)	Specification Implementation (Current)	Fogg Model Impact
Primary Card CTA	Conflicting weights: 1 solid blue button vs. 5 ghost outlines.	Standardized high-contrast orange CTA button (Broneeri) across all cards.	Trigger / Prompt: Clear, consistent, and predictable invitation to act.
Next Availability	Hidden deep inside profile pages.	Prominent availability badge placed on the card surface (Vaba täna / Järgmine: 16. sept).	Ability + Timing: Eliminates scheduling uncertainty.
Ratings & Credibility	Uniform "5.0" scores without review volume.	Granular ratings paired with verified review counts (e.g., 4.9 (98 arvustust)).	Motivation: Authentic social proof.
Sorting Controls	Generic text lacking criteria focus.	Structured price sorting (Sorteeri: Hinde järgi) connected with district filters.	Ability: Reduces manual comparison effort.
Engineering Foundation	Fragmented static page layouts.	Isolated, reusable UI kit covering complete state logic.	Scalability: Streamlines production deployment into modern frontend stacks.

4. Key Takeaway for UX Designers

Effective product design is not about redrawing entire pages on a whim. It is about crafting **modular design primitives** that adapt interface logic through design tokens and component props. Unifying action buttons into a coherent primary CTA and surfacing immediate booking availability directly on the card surface drives far higher conversions than completely rebuilding layout grids.
